

# SEARCHING

- the dictionary ADT
- binary search
- binary search trees

Searching

1

## The Dictionary ADT

- a dictionary is an abstract model of a database
- like a priority queue, a dictionary stores key-element pairs
- the main operation supported by a dictionary is searching by key
- simple container methods:
  - `size()`
  - `isEmpty()`
- query methods:
  - `findElement(k)`
  - `findAllElements(k)`
- update methods:
  - `insertItem(k, e)`
  - `remove(k)`
  - `removeAll(k)`
- special object
  - `NO SUCH KEY`, returned by an unsuccessful search

## Implementing a Dictionary with a Sequence

- unordered sequence:

- searching takes  $O(n)$  time
- inserting takes  $O(1)$  time

- ordered sequence

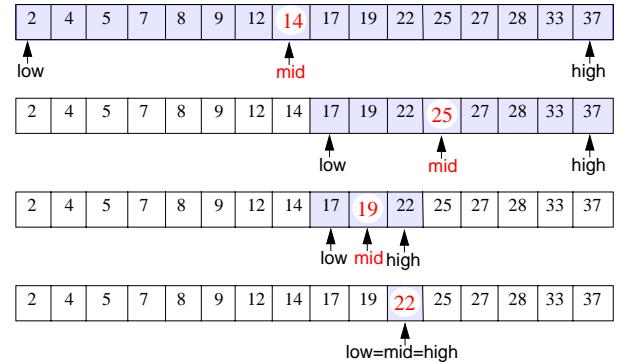

- searching takes  $O(1)$  time
- inserting takes  $O(n)$  time

- in the ordered sequence implementation, we can search faster if the sequence is array-based ...

## Binary Search

- narrow down the search range in stages
- “high-low” game
- `findElement(22)`

## Pseudo-code for Binary Search

```
Algorithm BinarySearch(S, k, low, high)
if low > high then
    return NO SUCH KEY
else
    mid ← (low+high) / 2
    if k = key(mid) then
        return key(mid)
    else if k < key(mid) then
        return BinarySearch(S, k, low, mid-1)
    else
        return BinarySearch(S, k, mid+1, high)
```

Searching

5

## Running Time of Binary Search

- the range of candidate items to be searched is halved after comparing the key with the middle element

comparison	search range
0	n
1	n/2
2	n/4
...	...
$2^i$	$n/2^i$
$\log_2 n$	1

- in the array-based implementation, access by rank takes  $O(1)$  time, thus binary search runs in  $O(\log n)$  time
